2. (30 pts.) An ideal Carnot refrigerator operates between temperature reservoirs of -6° C and 25°C. If the refrigerator uses 100 Watts to run (i.e. the rate at which work is done on the refrigerator is 100 Watts) how long will it take to change 0.4 kg of water initially at 25°C to ice at -6° C?

Some data:

specific heat of water = $4190 \text{ J/kg} \cdot \text{K}$ specific heat of ice = $2100 \text{ J/kg} \cdot \text{K}$ latent heat of fusion of water = $3.33 \times 10^5 \text{ J/kg}$

Tc= 267.15K

2. (30 pts.) An ideal Carnot refrigerator operates between temperature reservoirs of -6° C and 25°C. If the refrigerator uses 100 Watts to run (i.e. the rate at which work is done on the refrigerator is 100 Watts) how long will it take to change 0.4 kg of water initially at 25°C to ice at -6° C?

Some data:

specific heat of water = 4190 J/kg·K specific heat of ice = 2100 J/kg·K

latent heat of fusion of water = 3.33×10^5 J/kg

1st: find Qc= heat required to freeze water at 25°C into ice at -6°C.

Qc= mc DT- mLp+mc. DT:

= 0.4 [4190 (0-25) - 3.33 x105

+ (2100)(-6-0)] = 180,140 J

W=? Use K= Qc => W= Qc

K= K carnor = Tc = 267.15 = 267.15 = 267.15 = 8.62

W = Qc = 180,140 = 20,900 J.

Power: P= 100W= 100 = = W

t= = [2090]
